theory Soundness-Conceptual-Table
imports Soundness-Partial-Merkle

```

begin

Conceptual Merkle tables.

This layer deliberately does not reconstruct a complete *created-tree* witness from sampled openings. Instead it records the value that is uniquely authenticated for a root, length, and index in a hash-map state. Values at unauthenticated indices are arbitrary Hilbert-choice defaults; later proofs must only use them after showing agreement with authenticated openings or charging disagreement to a Merkle/hash side event.

The intended prefix-fixed use is to build these tables from the query-prefix oracle state, before the query-index challenge is sampled. Later openings checked by the verifier are handled in a downstream layer via pullback or controlled collision/inconsistency events.

theory Soundness-Conceptual-Query-Prefix
  imports Soundness-Conceptual-Table
begin

```

Prefix-fixed conceptual tables.

These tables are built from a staged query-prefix state, i.e. after the transcript prefix and earlier query rounds have been processed, but before the next query-index challenge is sampled. This is the state selection needed for later dynamic query-target bounds.

```

theory *Soundness-Conceptual-Query-Target*

imports

Soundness-Conceptual-Query-Prefix

Soundness-Aligned-Partial-Query-Prefix

begin

Prefix-fixed query targets built from conceptual Merkle tables.

This layer deliberately uses only the query-prefix state. It therefore supports the dynamic query-index probability bound, but it does not claim that openings first authenticated after the query challenge agree with these tables. That later-opening bridge is a separate proof obligation.

begin

```

Structured current-query Merkle path-output events.

The broad *checked-staged-security-with-query-prefix-current-path-output-hit-at* event intentionally forgets why the path was relevant. This layer keeps the authenticated-opening root, length, and final-state authentication evidence, so later Merkle/candidate argu-

ments can distinguish ordinary verifier hashing from candidate drift.

theory *Soundness-Staged-Aligned-Current-Query*
imports *Soundness-Staged-Aligned-Partial-Merkle*
begin

Thin wrappers that expose the actual-alpha current-query event in the aligned partial-candidate soundness path. The underlying query reduction still lives in the partial-Merkle layer; this theory only uses the projection proved in the current-query alignment layer.

theory Soundness-Conceptual-Query-Current-Alpha-Clean
imports Soundness-Staged-Aligned-Current-Query-Path
begin

```

Alpha-clean wrappers for the default-backed conceptual current-query route.

This layer derives the default-context non-consistency premise from the false statement, low degree of the fixed default tables, and the fact that the sampled alpha vector is not in the corresponding composition bad set.

Soundness-Conceptual-Query-Current-Alpha-Clean

Soundness-Staged-Aligned-Partial-Merkle

begin

Packaging for the aligned-transcript partial-candidate path with the current-empty query bound. This combines the current-query non-empty branch with the empty-composition branch introduced in the current-empty query layer, using a refined empty-header query bound in this downstream route.

context soundness

theory Staged-Security-Experiment-Composition-Query-Canonical
imports Staged-Security-Experiment-Composition-Query-Classification
begin

```

Canonical-index projections for the header-authenticated composition query bridge. These lemmas do not bound the broad existential event by themselves; they expose the canonical query-index cover that a later Merkle/candidate binding argument has to control. In particular, the projection from the actual-alpha-prefix event to a query-prefix hit is support-level evidence. It is not by itself a probability reduction to the separately sampled query-prefix program: the authenticated opening witness is still selected existentially from verifier-reachable evidence. A sound probability bound needs either a cover fixed before the query challenge is sampled, or a Merkle/collision/partial-opening side event accounting for failure to select such a witness.

begin

Bridge from the broad actual-alpha diagnostic witness event to a fixed query-prefix candidate-pair witness event.

The bridge is deterministic: it extracts the concrete prefix branch and candidate pair already present in the diagnostic event. It does not bound the diagnostic event probabilistically; later proof layers must still avoid treating the broad existential diagnostic event as a final public-path event.

theory Soundness-Relevant-Drift-Public
imports
  Soundness
  Soundness-Staged-Empty-Relevant-Drift
begin

```

Public migration wrappers for the refined relevant-drift route.

These theorems sit downstream of *Soundness* so the main public compatibility layer does not keep growing. The route below derives the aligned composition-randomization branch and aligned query branch from the same per-round current-query prefix bounds. It exposes only the empty-header-specific relevant-drift event and keeps the partial-candidate FRI premises internal to this route.

```

theory Soundness-Relevant-Drift-Reachable-FRI
imports Soundness-Relevant-Drift-Public
begin

```

Reachable partial-candidate FRI interface for the refined relevant-drift migration path. This layer does not change the compatibility predicates *trace-fri-bad-with-partial-openings* and *composition-fri-bad-with-partial-openings*. Instead it records the partial-candidate FRI obligations used by the aligned partial-opening route: the verifier has authenticated sampled openings, and the FRI low-degree interface rules out a low-degree violation for any candidate table compatible with those openings.

These wrappers expose the broad witnessed cross/Merkle diagnostic split used during development of the reachable-FRI route. They remain available only as internal plumb-

ing; the public route should use aligned transcript-indexed wrappers that do not expose these diagnostic events.

theory *Soundness-FRI-Partial-Evidence*

imports *Soundness-Relevant-Drift-Reachable-FRI*

begin

Normalized partial-opening FRI evidence predicates for the reachable-state FRI obligations.

This theory is intentionally narrow. It does not change the public soundness theorem path; it only factors the remaining reachable FRI obligations into explicit evidence predicates that later proofs can target.

theory Soundness-FRI-Layer-Evidence
  imports Soundness-FRI-Partial-Evidence
begin

```

Partial FRI layer evidence extracted from the verifier transcript.

This theory only packages facts already exposed by the trace and composition layer-opening lemmas for *accepted-fri-opening-transcript*. It does not reconstruct complete FRI tables from sampled openings.

theory Soundness-FRI-Generic-Low-Degree

imports *Soundness-FRI-Layer-Evidence*
begin

Generic FRI low-degree proof interface.

This theory factors the trace/composition-independent bad-challenge-list layer. It deliberately stays at the generic FRI level: no trace-specific or composition-specific candidate predicate is mentioned here.

context *soundness*
begin

```

Internal concrete FRI challenge-list bounds.

These lemmas deliberately avoid the symbolic parameters *trace-fri-error* and *composition-fri-error*. They expose the concrete bad-set fractions obtained from the generic FRI bad challenge-list interface. Later public-route work can either use these concrete terms directly, or relate the symbolic error parameters to these terms via an explicitly chosen FRI soundness interface.

Refined reachable FRI layer-chain targets.

Broad reachable partial-candidate events quantify full base tables compatible with sampled initial openings. Sampled base openings alone do not determine the committed FRI layer chain, so this theory introduces the narrower algebraic cover used by the next proof layer.

Its witnesses include the accepted FRI opening transcript and a canonical FRI layer chain. The cover is internal proof infrastructure; it does not change the protocol, verifier, Merkle interface, or public theorem assumptions.

theory *Soundness-FRI-Sampled-Obstructions*
imports *Soundness-FRI-Full-Cover-Domains*
begin

Explicit obstruction events for the branch where an accepting verifier execution reaches the broad reachable FRI bad event, but no sampled FRI layer-chain witness exists.

These predicates are proof-routing devices only. They do not reconstruct complete FRI tables from sampled openings; they record that the verifier's partial FRI evidence cannot be organized into the sampled layer-chain object required by the generic low-degree reduction.

theory Soundness-FRI-Zero-Round-Target
  imports Soundness-FRI-Sampled-Assignment-Chain
begin

```

Query-style target events for the zero-round FRI branch.

If no FRI fold round is present, sampled fold equations cannot produce a successor layer. Acceptance can only test that sampled base-layer entries agree with the final value. This theory factors the corresponding target set without changing the protocol or the public soundness interface.

Verifier-tied FRI partial-candidate events.

Broad reachable partial-candidate events allow the candidate table to be compatible with sampled authenticated openings whose indices are not tied to the FRI opening transcript. This theory introduces narrower internal events where the candidate openings use the same query indices as the verifier's FRI transcript. The protocol and public soundness statement are unchanged.
