theory *Soundness-Not-Prefix-Partial-Opening*
imports *Soundness-Relevant-Drift-Transcript-Public*
begin

Same-run partial-opening packaging for the remaining not-prefix residual.

The residual is not a probability-small sparse-cover event by itself. Instead, it records the precise verifier evidence still carried by the current route: an accepting verifier run, authenticated partial trace openings from that same run, and a trace-domain index left unopened by those sampled openings. This layer gives that evidence a non-diagnostic name and keeps the broad witnessed cross/Merkle classifier out of the checked wrapper.

theory Soundness-FRI-Layer-Merkle
imports Soundness-FRI-Header-Tied-Reduction
begin

```

Authenticated-opening facts for sampled FRI layer chunks.

The sampled-assignment conflict predicates are stated over transcript chunks. This layer connects those chunks back to the Merkle checks performed by the verifier. It is intentionally local: it extracts only sampled openings from the verifier execution and does not reconstruct complete FRI tables.

theory Soundness-FRI-Layer-Authenticated
imports Soundness-FRI-Layer-Merkle
begin

```

Authenticated FRI layer evidence paired with transcript layer evidence.

The exact equality between the layer chunk recorded in *accepted-fri-opening-transcript* and the layer chunk authenticated by the verifier is still intentionally not asserted here. Instead this theory packages the checked facts that are currently available without a broad replay induction: the transcript gives a local FRI step, and the verifier execution gives an authenticated FRI chunk at the same root, layer length, and replayed query index.

theory Soundness-FRI-Recorded-Chunk-Replay
imports Soundness-FRI-Raw-Layer-Bounds
begin

```

Selected recorded FRI layer replay.

The authenticated-route layer already proves that the verifier authenticates some chunk at the replayed root/index of a selected FRI layer. The residual proofs need the stronger fact that the specific chunk recorded in the extracted verifier transcript is authenticated. This theory proves that narrow replay fact for one selected layer, avoiding the earlier broad all-layer replay induction.

imports

Soundness-FRI-Authenticated-Route
Soundness-FRI-Base-Recorded-Chunk
Soundness-FRI-Final-Step-Replay
Soundness-FRI-Raw-Layer-Bounds
Soundness-FRI-Recorded-Chunk-Replay

begin

Narrow residual refinements for the verifier-tied composition FRI route. This layer keeps the larger authenticated route theory stable while naming the exact remaining base-opening gap: the recorded first-layer composition FRI chunk is not known to be authenticated.

theory Soundness-FRI-Value-Aligned-Events
  imports Soundness-FRI-Composition-Residuals
begin

```

Value-aligned FRI branch events.

These events are narrower than the raw sampled base-opening conflicts: they keep the trace query opening that supplies the first trace FRI input value. The intended use is to avoid exporting broad verifier-query-round decomposition lemmas, which are expensive for Isabelle to finalize.

```

Soundness-FRI-Value-Aligned-Events

Soundness-FRI-Final-Step-Replay

Soundness-FRI-Recorded-Chunk-Replay

begin

Narrow residual refinements for the header-tied trace FRI route. These predicates name the remaining replay gaps for non-base FRI branches without changing the protocol or exporting broad selected-step replay lemmas.

imports

Soundness-FRI-Trace-Candidate-Gap

Soundness-FRI-Composition-Support

begin

Small destructors for the remaining FRI candidate-transfer branches. These branches are intentionally not closed by complete-table uniqueness: sampled partial openings can admit multiple completions. The lemmas here expose the exact low/non-low candidate shape that later proofs must charge to a partial-opening inconsistency or a narrower candidate-indexed event.

  Soundness-FRI-Empty-Header-Reduction

```

begin

Staged packaging for the active FRI reductions used by the public route. This layer does not add assumptions; it names the exact verifier-local reductions consumed by the public-route bounds.

Internal symbolic FRI soundness interface for the public staged theorem.

The trace side is intentionally stated in terms of the verifier-consumed header-tied branch and the empty-composition-header branch. The composition side is stated in terms of the verifier-tied branch consumed by the active public route.

```

Verifier-local FRI challenge prequery accounting.

The concrete FRI challenge-list bounds require freshness of future Trace/Composition FRI challenge keys. In the staged adversary experiment the verifier receives the adversary's final oracle map, so freshness is not automatic. This layer defines the exact verifier-header key paths and proves deterministic fresh/prequeried splits. It does not add assumptions or change the oracle model.

theory Soundness-FRI-Staged-Active-Bounds
  imports Soundness-FRI-Prequery-Composition-Sampled-Bounds

```

begin

Staged integration lemmas for the active FRI route.

The prequery accounting layer proves whole checked-security-experiment bounds for sampled FRI layer-chain events. The active route still reasons about partial-candidate FRI events. This layer bridges those levels by splitting a partial-candidate FRI bad event into the sampled layer-chain case and the remaining missing-sampled-chain residual.

theory Soundness-FRI-Trace-Untied-Cases
  imports Soundness-FRI-Trace-Candidate-Blocker
begin

```

Case split for the remaining trace FRI untied-witness residual.

The broad residual says that the reachable low-degree witness consumed by the verifier and the separate non-low-degree reachable witness disagree in at least one of: authenticated root, query-index list, or sampled openings. This theory exposes these three causes as separate events so subsequent proof layers can bound them independently.

theory *Soundness-FRI-Trace-Sibling-Evidence*
 imports *Soundness-FRI-Value-Aligned-Events*
begin

Proof-only refinement of the trace FRI sibling mismatch branch.

The existing trace candidate predicate records agreement with the trace-query openings only. The first trace FRI sibling value is read from the FRI layer transcript, so the sibling branch cannot be closed from the current candidate predicate alone. This theory isolates the exact missing evidence: a trace candidate must also agree with the recorded first-layer FRI sibling values.
