theory Soundness-FRI-Full-Cover-Active-Bounds
imports
  Soundness-FRI-Obligation-Normalization
  Soundness-FRI-Full-Cover-Domains
begin

```

Compact active-route bridges for the full-cover FRI split.

The imported layers already prove:

- a full-cover challenge-list/envelope bound;

- a missing-full-cover domain split;
- active trace/composition residual adapters.

This theory only packages those ingredients in the shape consumed by the same-run public soundness route. It does not add protocol assumptions or change the FRI model.

theory *Soundness-FRI-Full-Cover-Staged-Bounds*

imports

Soundness-FRI-Prequery-Composition-Sampled-Bounds

Soundness-FRI-Full-Cover-Active-Bounds

begin

Staged bounds for the full-cover FRI split.

Unlike the verifier-local full-cover envelope lemmas, these results work in the staged adversary experiment where future FRI keys may have been queried by the attacker. The full-cover part is therefore routed through the existing staged fresh/prequery accounting for FRI challenge-list hits.

theory *Soundness-FRI-Derived-Active-Reductions*

imports

Soundness-FRI-Staged-Replay-Bounds

Soundness-FRI-Full-Cover-Staged-Bounds

begin

Derived active-FRI packaging.

This layer keeps the near-threshold staged replay theory stable. It packages the already proved trace and composition verifier-state reductions into the active-FRI interface consumed by the public route. It does not add protocol assumptions or change the FRI model.

```

Sampled-query FRI interface.

This theory names the FRI bad-candidate event that matches the verifier's sampled evidence: authenticated partial openings, sampled fold checks on the canonical domains, final consistency, and a non-low-degree candidate. It is deliberately separate from the full-cover compatibility route, where sampled openings are temporarily strengthened to full fold-index coverage.

[of low-degree candidate-bad degree-bound]
by *force*

Fallback sanity bound: the restricted projection is always a subset of the full challenge space. This lemma is intentionally not the main FRI low-degree theorem; the useful symbolic bounds must come from a sharper sampled-query FRI argument.

The following bounds expose the current internal sampled-FRI interface: a sampled layer-

chain cover plus a bad-set envelope implies a challenge-list hit, which is then bounded by the existing Fiat-Shamir challenge-list calculus. The cover and envelope parameters are internal proof-layer interfaces; they are not public protocol assumptions.

imports Soundness-FRI-Sampled-Interface
begin

```

Staged query-index accounting for FRI query-list events.

The verifier-local exact query-list bounds still assume query freshness of the transferred verifier state. This layer charges accepted FRI query-list hits to the checked staged transcript query-index target event, using only the query indices actually derived by the verifier.

theory Soundness-Public-Route-Active-Base
imports
  Soundness-Public-Route-Single-Query
  Soundness-FRI-Query-Exact-Bounds
  Soundness-FRI-Query-Index-Staged-Bounds
begin

```

Base active-FRI public-route endpoint.

This theory is deliberately upstream of the downstream FRI route adapters. It exposes the common route theorem from staged active FRI event bounds, without importing the final same-run endpoint theory. This avoids an import cycle when later route layers are consumed by the final public endpoint.

theory Soundness-Public-Route-Same-Run
imports
  Soundness-Public-Route-Active-Base
  Soundness-FRI-Sampled-Interface-Conflict-Zero
begin

```

Public-route infrastructure for the staged soundness theorem. This layer assembles the checked current-empty and transcript-empty reductions and states them in the plain locale *soundness*. FRI losses are expressed as concrete staged verifier-event probabilities that are bounded in later FRI layers.

```

  imports
    Soundness-FRI-Query-Index-Staged-Bounds
    Soundness-FRI-Query-Aware-Interface
  begin

  Staged sampled-query FRI bounds from generic query fibers.

  The checked staged query-index accounting currently consumes a fixed query target.
  This layer derives such a target from the union of the generic per-challenge query fibers
  outside a chosen challenge-list cover. It keeps the query-aware FRI boundary explicit
  without changing the protocol or the random-oracle model.

  context soundness

end

Query-list prequery accounting for sampled FRI.

The exact verifier-local sampled-query bounds are list-valued: they bound the probability of drawing a whole query-index list from a target set. In the staged adversary experiment the verifier reuses the adversary's oracle map, so an exact staged theorem needs a fresh/prequeried split for the whole query-index list. This layer provides the conservative relation-budget side of that split without changing the oracle model.

theory *Soundness-FRI-Query-Challenge-Fresh-Split*
imports *Soundness-FRI-Query-Fiber-Exact-Staged-Bounds*
begin

Staged split for FRI query/challenge pair events.

The exact pair-fraction route must keep the query/challenge pair event until the challenge-list probability has been accounted for. This layer separates only the challenge prequery side event, leaving the fresh branch as the original pair hit conjoined with path freshness of the relevant FRI challenge keys.

context *soundness*
begin

theory Soundness-FRI-Query-Challenge-Trace-Staged-Product
imports Soundness-FRI-Query-Challenge-Actual-Product
begin

```

Trace-side staged product accounting for the challenge-fresh/query-path-fresh FRI pair branch.

This theory is intentionally narrow. The preceding layer contains the verifier-local actual-fresh product bounds and the raw-list path bridges. Here we package the trace bridge into staged fixed-challenge and finite-cover product bounds.

begin

```

Generic sampled-query FRI challenge-cover reductions.

This layer is deliberately independent of trace/composition naming. The intended later FRI low-degree proof has to show that every sampled bad candidate produces a challenge list in an algebraic multiround bad set. The lemmas here turn exactly that fact, plus local round cardinality bounds, into the finite-cover/fraction interface consumed by the staged route.

```

theory Soundness-FRI-Zero-Round-Query-List-Bounds
imports
  Soundness-FRI-Zero-Round-Target
  Soundness-FRI-Query-List-Exact-Product
begin

```

Exact staged query-list bounds for fixed zero-round FRI targets.

The target table and final value must already be fixed before query sampling. This theory deliberately does not close the remaining candidate/verifier alignment gap; it only packages the exact-product query accounting for the fixed targets isolated in *Soundness-FRI-Zero-Round-Target*.

theory *Soundness-FRI-Zero-Round-Agreement-Set-Bounds*
imports *Soundness-FRI-Zero-Round-Query-List-Bounds*
begin

Global agreement-set bound for the zero-round trace FRI target.

The verifier-local event *trace-fri-zero-round-query-list-target-hit* is existential in a candidate table and final value. The query-list target depends on these witnesses only through the agreement set inside *query-sample-space*. This layer replaces the arbitrary-list existential by a finite union over agreement sets, preserving the exact query-list product accounting for each fixed set.

imports
  Soundness-FRI-Trace-Untied-Cases
  Soundness-FRI-Zero-Round-Query-List-Bounds
begin

```

Verifier-tied normalization for the empty-composition-header trace FRI branch.

The broad empty-header branch can carry a non-low candidate built from existential partial openings. This layer separates that branch into the verifier-checked zero-round obstruction, Merkle inconsistency, or the existing candidate-transfer residual. It deliberately avoids complete-table reconstruction from sampled openings.

Soundness-FRI-Trace-Empty-Verifier-Tied

begin

First-stage API for sharpening the concrete FRI endpoint.

The public endpoint already removed the FRI soundness assumptions by using explicit staged verifier-event error definitions. This theory factors those definitions into named challenge, full-cover/domain, conflict, and zero-round components. At this stage the components are definitionally equal to the endpoint terms; later proof layers can replace individual components by sharper product/fiber or residual sums without touching the public theorem interface.

theory Soundness-FRI-Canonical-Full-Cover-Failure
  imports Soundness-FRI-Sampled-Challenge-Cover
begin

```

Canonical full-cover failure events for sampled-query FRI.

The broad sampled full-cover failure predicates quantify over arbitrary domain witnesses. The sampled-query split, however, produces the failure on the canonical FRI domains.

This layer names that narrower event so later bounds do not have to prove facts about unused arbitrary domain entries.

imports Soundness-FRI-Trace-Candidate-Blocker
begin

```

Trace-only verifier-consumed FRI evidence.

The broad reachable trace FRI predicate is root-parametric: it accepts any authenticated trace root present in the final verifier state. This layer names the verifier-consumed alternative, where the trace root and query indices are those appearing in the accepted FRI opening transcript. It does not change the protocol or the public theorem interface.

```

First split for the remaining plain trace empty-branch sampled-assignment conflict. The plain event is intentionally broader than the low-degree sampled-query bad-candidate event: it does not require the conflicting candidate table to be non-low-degree. This layer separates the aligned verifier-tied part from the residual that still needs a Merkle/replay explanation.

theory *Soundness-FRI-Trace-Restricted-Query-Endpoint*

imports *Soundness-FRI-Trace-Empty-Sampled-Assignment-Split*

begin

Public entry point for the staged STARK soundness theorem. The theorem in this theory combines the staged adversary experiment, Merkle authentication reductions, query bounds, composition randomization bounds, and the FRI query/challenge accounting into one explicit probability bound.

The bound uses restricted trace and composition product-accounting terms and the proved zero-round trace empty-header estimates from the preceding FRI theories.
